

1. CLASSIFICATION OF MATTER

1.1 Physical classification: It is based on physical state under ordinary conditions of temperature and pressure, matter is classified into the following three types:

(a) Solid (b) Liquid (c) Gas

(a) Solid: A substance is said to be solid if it possesses a definite volume and a definite shape
E.g. sugar, iron, gold, wood etc.

(b) Liquid: A substance is said to be liquid if it possesses a definite volume but not definite shape. They take up the shape of the vessel in which they are put.
E.g. water, milk, oil, mercury, alcohol etc.

(c) Gas: A substance is said to be gas if it neither possesses a definite volume nor a definite shape. This is because they fill up the whole vessel in which they are put.
E.g. hydrogen(H_2), oxygen(O_2), carbon dioxide(CO_2), etc.

1.2 Chemical classification:

On the basis of chemical nature matter is classified into the following two types :

(a) Pure Substance (b) Mixture

(a) Pure Substance: When all constituent particles of a substance are same in chemical nature, it is said to be a pure substance. Two type of pure substances:

(i) Element (ii) Compound

(i) Element: an element consist of only one type of atoms. These particles may exist as Atoms or molecules. **E.g.** O_2 , P_4 , S_8 , etc.

(ii) Compound: When two or more atoms of different elements combine together in a definite ratio. **E.g.** water, ammonia, carbon dioxide, sugar, etc.

(b) Mixture: A mixture contains many types of particles. A mixture contains particles of two or more pure substances which may be present in it in any ratio. Hence, their composition is variable. Pure substances forming mixture are called its components. Many of the substances present around you are mixtures. For example, sugar solution in water, air, tea, etc., are all mixtures.
Two types of mixtures:

(i) Homogeneous mixture

(ii) Heterogeneous mixture

- (i) **Homogeneous mixture:** The components completely mix with each other. This means particles of components of the mixture are uniformly distributed throughout the bulk of the mixture and its composition is uniform throughout. E.g.: Sugar solution, air
- (ii) **Heterogeneous mixture:** In a heterogeneous mixture, the composition is not uniform throughout and sometimes different components are visible. E.g.: mixtures of salt and sugar, grains and pulses along with some dirt (often stone pieces)

2. INTRODUCTION:

There are a large number of objects around us which we can see and feel. It was John Dalton who firstly developed a theory on the structure of matter, later on which is known as Dalton's atomic theory.

2.1. DALTON'S ATOMIC THEORY:

- (i) Each element is composed of extremely small particles called atoms which can take part in chemical combination.
- (ii) All atoms of a given element are identical i.e., atoms of a particular element are all alike but differ from atoms of other elements.
- (iii) Atoms of different elements possess different properties (including different masses).
- (iv) Atoms are indestructible i.e., atoms are neither created nor destroyed in chemical reactions.
- (v) Atoms of elements combine to form molecules and compounds are formed when atoms of more than one element combine.
- (vi) In a given compound, the relative number and kind of atoms is constant.

2.2. **Atomic mass:** It is the average relative mass of atom of element as compared with times the mass of an atom of carbon-12 isotope.

$$\text{Atomic mass} = \frac{\text{Average mass of an atom}}{1/12 \times \text{Mass of an atom of } C^{12}}$$

$\frac{1}{12}$ of the mass of an atom of carbon-12 equals to 1.66×10^{-24} gm and is also assigned 1amu

2.3. **Gram atomic mass (GAM):** Atomic mass of an element expressed in grams is called Gram atomic mass or gram atom or mole atom.

(i) Number of gram atoms = $\frac{\text{Mass of an element}}{\text{GAM}}$

(iii) Number of atoms in 1 GAM = 6.02×10^{23}

Number of atoms in a given substance = No. of gram atoms $\times 6.02 \times 10^{23}$

(v) Mass of one atom of the element (in g) = $\frac{\text{GAM}}{6.02 \times 10^{23}}$

2.4. Molecular mass: Molecular mass of a molecule, of an element or a compound may be defined as a number which indicates how many times heavier is a molecule of that element or compound as compared with $\frac{1}{12}$ of the mass of an atom of carbon-12.

$$\text{Molecular mass} = \frac{\text{Mass of one molecule of the substance}}{1/12 \times \text{Mass of one atom of C-12}}$$

$$\text{mass of one molecule} = \text{Molecular mass} \times 1.67 \times 10^{-24} \text{ g}$$

Molecular mass of a substance is the additive property and can be calculated by adding the atomic masses of atoms present in one molecule.

2.5. Gram molecular mass (GMM) : Molecular mass of an element or compound when expressed in g is called its gram molecular mass, gram molecule or mole molecule.

$$\text{Number of gram molecules} = \frac{\text{Mass of substance}}{\text{GMM}}$$

$$\text{Mass of substance in g} = \text{No. of gram molecules} \times \text{GMM}$$

Element	(Atomic Mass)	(mass of one atom)	Gram Atomic mass
N	14	14 amu	14 gm
He	4	4 amu	4 gm
C	12	12 amu	12 gm

2.6. Mole

One mole of any substance contains a fixed number (6.023×10^{23}) of any type of particles (atoms or molecules or ions) and has a mass equal to the atomic or molecular weight, in grams. Thus it is correct to refer to a mole of helium, a mole of electrons or a mole of any ion, meaning respectively Avogadro's number of atoms, electrons or ions.

Methods of Calculations of mole:

(1) If no. of some species is given, then no. of moles = $\frac{\text{Given no}}{N_A}$

(2) If weight of a given species is given, then no. of moles = $\frac{\text{Given wt.}}{\text{Atomic wt.}}$ (for atoms),

or = $\frac{\text{Given wt.}}{\text{Molecular wt.}}$ (for molecules)

(3) If volume of a gas is given along with its temperature (T) and pressure (P).

$$PV = nRT \quad (n : \text{Number of moles of gas})$$

P (Pressure of gas): Pressure of the gas is the force exerted by the gas per unit area of the walls of the container in all directions.

$$\text{Thus, Pressure (P)} = \frac{\text{Force(F)}}{\text{Area(A)}} = \frac{\text{Mass(m)} \times \text{Acceleration(a)}}{\text{Area(A)}}$$

Name	Symbol	Value
Bar	bar	1 bar = 10^5 Pa
Atmosphere	atm	1 atm = 1.01325×10^5 Pa
Torr	Torr	1 Torr = $\frac{101325}{760}$ Pa \times 133.322 Pa
millimeter of mercury	mm Hg	1 mm Hg = 133.322 Pa

V (Volume of gas): Volume is expressed in liters (L), milliliters (mL) or cubic centimeters (cm^3), cubic meters (m^3).

$$1 \text{ m}^3 = 10^3 \text{ dm}^3 = 10^6 \text{ cm}^3 = 10^6 \text{ mL} = 10^3 \text{ L}$$

T (Temperature of gas): S.I. unit of temperature is Kelvin (K).

$$T(\text{K}) = t(^{\circ}\text{C}) + 273.15$$

R (Universal gas constant) : Values of $R = 0.082 \text{ LatmK}^{-1}\text{mol}^{-1}$

$$= 8.314 \text{ JK}^{-1}\text{mol}^{-1}$$

$$= 1.987 \text{ CalK}^{-1}\text{mol}^{-1}$$

1 mole of ions is also termed as 1 g ion

1 mole of molecule is also termed as 1 gmolecule

Ans. 1.9×10^6 years (approx)

Sol. 10^{10} grains are distributed in 1 second

$$6.02 \times 10^{23} \text{ grains are distributed in } \frac{6.02 \times 10^{23}}{10^{10}} \text{ sec} = \frac{6.02 \times 10^{23}}{10^{10} \times 60 \times 60 \times 24 \times 365} \text{ years}$$

$$= 1.9 \times 10^6 \text{ years (approx.)}$$

Ex.2 How many atoms are there in 100 amu of He ?

Ans. 25

Sol. We know that, $1 \text{ amu} = \frac{1}{12} \times \text{weight of one } ^{12}\text{C atom}$

or weight of one ^{12}C atom = 12 amu (at. wt. of C = 12 amu).

Similarly, as the atomic weight of He is 4

weight of one He atom = 4 amu.

Thus, the number of atoms in 100 amu of He = $\frac{100}{4} = 25$.

Ans. 68

Sol. 1 liter Hg metal

volume = 1000

$$d = \frac{m}{v} \quad \text{mass} = d \times V = 13.6 \times 1000$$

$$\text{No of mole of Hg metal} = \frac{13.6 \times 1000}{200} = 68 \text{ mole}$$

Sol. number of mole = $\frac{0.09}{18}$

$$\text{so number of molecules} = \frac{0.09}{18} \times N_A = 3.01 \times 10^{21}.$$

Ex.5 A sample of ethane has the same mass as 10.0 million molecules of methane. How many C₂H₆ molecules does the sample contain?

Ans. 5.34×10^6

Sol. Let the number of C₂H₆ molecules in the sample be n. As given, mass of C₂H₆ = mass of 10⁷ molecules of CH₄

$$\frac{n}{N_A} \times \text{mol. wt. of C}_2\text{H}_6 = \frac{10^7}{N_A} \times \text{mol. wt. of CH}_4$$

$$\frac{n}{N_A} \times 30 = \frac{10^7}{N_A} \times 16$$

$$n = 5.34 \times 10^6.$$

5 mole of H₂SO₄ have mole of 'H' atom = 10

Total mole of 'H' atom = 40

mole of H₂ = 20

$$n = \frac{2 \times 0.350}{0.0821 \times 273} =$$

$$n = \frac{\text{Weight}}{\text{Atomic mass}}$$

Atomic mass = 16 amu

Ex.8 Oxygen is present in a 1-litre flask at a pressure of 7.6×10^{-10} mm of Hg at 0°C. Calculate the number of oxygen molecules in the flask.

Ans. 0.44×10^{-13} .

Sol. Pressure = 7.6×10^{-10} mm

= atm (1 atm = 76 cm) = 10^{-12} atm.

Volume = 1 litre, R = 0.0821 lit. atm/K/mole, temperature = 273 K.

We know that $PV = nRT$ or $n = \frac{PV}{RT}$

$$n = \frac{10^{-12} \times 1}{0.082 \times 273} = 0.44 \times 10^{-13}$$

3. LAWS OF CHEMICAL COMBINATION:

Antoine Lavoisier, John Dalton and other scientists formulate certain laws concerning the composition of matter and chemical reactions. These laws are known as the law of chemical combination.

3.1 THE LAW OF CONSERVATION OF MASS:

It is given by Antoine Lavoisier.

In a chemical change total mass remains conserved that is mass before reaction is always equal to mass after reaction.

Before reaction initially 1 mole $\frac{1}{2}$ mole

After the reaction 0 0 1 mole

mass before reaction = mass of 1 mole $\text{H}_2 (\text{g})$ + mass of $\frac{1}{2}$ mole $\text{O}_2 (\text{g})$

$$= 2 + 16 = 18 \text{ g}$$

mass after reaction = mass of 1 mole water = 18 g

3.2 LAW OF CONSTANT OR DEFINITE PROPORTION:

It is given by Proust. All chemical compounds are found to have constant composition irrespective of their method of preparation or sources.

Example: In water (H_2O), Hydrogen and Oxygen combine in 2 : 1 molar ratio, the ratio remains constant whether it is tap water, river water or sea water or produced by any chemical reaction.

Ex.10 1.80 g of a certain metal burnt in oxygen gave 3.0 g of its oxide. 1.50 g of the same metal heated in steam gave 2.50 g of its oxide. Show that these results illustrate the law of constant proportion.

Sol. In the first sample of the oxide,

wt. of metal = 1.80 g,

wt. of oxygen = (3.0 – 1.80) g = 1.2 g

$$\frac{\text{wt. of metal}}{\text{wt. of oxygen}} = \frac{1.80\text{g}}{1.2\text{g}} = 1.5$$

In the second sample of the oxide,

$$\frac{\text{wt. of metal}}{\text{wt. of oxygen}} = \frac{1.50\text{g}}{1\text{g}} = 1.5$$

Thus, in both samples of the oxide the proportions of the weights of the metal and oxygen are fixed. Hence, the results follow the law of constant proportion.

3.3 THE LAW OF MULTIPLE PROPORTIONS:

It is given by Dalton.

When one element combines with the other element to form two or more different compounds, the mass of one element, which combines with a constant mass of the other, bear a simple ratio to one another.

Note: Simple ratio here means the ratio between small natural numbers, such as 1: 1, 1: 2, 1: 3, Later on this simple ratio becomes the valency and then oxidation state of the element.

Example: Carbon and Oxygen when combine, can form two oxides, CO (carbon monoxide), CO₂(Carbon dioxides)

In CO, 12 g carbon combined with 16 g of oxygen.

In CO₂, 12 g carbon combined with 32 g of oxygen.

Thus, we can see the mass of oxygen which combine with a constant mass of carbon (12 g) bear simple ratio of 16 : 32 or 1 : 2.

3.4 LAW OF RECIPROCAL PROPORTION:

It is given by Richter.

The ratio of the weights of two elements A and B which combine separately with a fixed weight of the third element C is either the same or simple ratio of the weights in which A and B combine directly with each other.

Example:

Ex.11 Ammonia contains 82.35% of nitrogen and 17.65% of hydrogen. Water contains 88.90% of oxygen and 11.10% of hydrogen. Nitrogen trioxide contains 63.15% of oxygen and 36.85% of nitrogen. Show that these data illustrate the law of reciprocal proportions.

Sol. In NH₃, 17.65g of H combine with N = 82.35g

$$1 \text{ g of H combine with N} = \frac{82.35}{17.65} \text{ g} = 4.67 \text{ g}$$

In H₂O, 11.10 g of H combine with O = 88.90 g

$$1 \text{ g of H combine with O} = \frac{88.90}{11.10} \text{ g} = 8.01 \text{ g}$$

Ratio of the weights of N and O which combine with fixed weight (=1g) of H

$$= 4.67 : 8.01 = 1 : 1.7$$

In N_2O_3 , ratio of weights of N and O which combine with each other = 36.85 : 63.15

$$= 1 : 1.7$$

Thus the two ratios are the same. Hence it illustrates the law of reciprocal proportions.

3.5 GAY-LUSSAC'S LAW OF COMBINING VOLUME:

According to him elements combine in a simple ratio of atoms, gases combine in a simple ratio of their volumes provided all measurements should be done in the same temperature and pressure

1 vol 1 vol 2 vol

3.6 AVOGADRO'S HYPOTHESIS:

Equal volumes of polyatomic all gases have equal number of molecules (not atoms) at same temperature and pressures conditions.

S.T.P. (Standard Temperature and Pressure)

At S.T.P. condition:

Temperature = 0°C or 273 K

Pressure = 1 bar

and volume of one mole of gas at STP is found to be equal to 22.7 litres which is known as molar volume.

4. STOICHIOMETRY AND STOICHIOMETRIC CALCULATIONS

The word 'stoichiometry' is derived from two Greek words — stoicheion (meaning, element) and metron (meaning, measure). Stoichiometry, thus, deals with the calculation of masses (sometimes volumes also) of the reactants and the products involved in a chemical reaction

Example: When potassium chlorate (KClO_3) is heated it gives potassium chloride (KCl) and oxygen (O_2).

- Remember a balanced chemical equation is one which contains an equal number atoms of each element on both sides of equation.

4.1 Interpretation of balanced chemical equations:

Once we get a balanced chemical equation then we can interpret a chemical equation by following ways

- (a) Mass - mass analysis
- (b) Mass - volume analysis
- (c) Mole - mole analysis
- (a) **Mole - mole analysis:**

This analysis is very much important for quantitative analysis point of view.

Now consider again the decomposition of KClO_3 .

In very first step of mole-mole analysis you should read the balanced chemical equation like **2 moles KClO_3 on decomposition gives you 2 moles KCl and 3 moles O_2** and from the stoichiometry of reaction we can write

$$\frac{\text{Moles of } \text{KClO}_3}{2} = \frac{\text{Moles of } \text{KCl}}{2} = \frac{\text{Moles of } \text{O}_2}{3}$$

Now for any general balance chemical equation like

you can write.

$$\frac{\text{Moles of A reacted}}{a} = \frac{\text{Moles of B reacted}}{b} = \frac{\text{Moles of C produced}}{c} = \frac{\text{Moles of D produced}}{d}$$

(b) Mass - mass analysis:

Consider the reaction $2 \text{KClO}_3 \longrightarrow 2\text{KCl} + 3\text{O}_2$ According to stoichiometry of the reaction mass-mass ratio : $2 \times 122.5 : 2 \times 74.5 : 3 \times 32$

$$\text{or } \frac{\text{Mass of } \text{KClO}_3}{\text{Mass of } \text{KCl}} = \frac{2 \times 122.5}{2 \times 74.5} \quad \frac{\text{Mass of } \text{KClO}_3}{\text{Mass of } \text{O}_2} = \frac{2 \times 122.5}{3 \times 32}$$

Ex.12 Consider the balanced reaction

What can be concluded from the coefficients of species in this balanced equation?

- (A) For this reaction, exactly 2 g of Cl_2O_7 must be taken to start the reaction
- (B) For this reaction, exactly 2 mol of Cl_2O_7 must be taken to start the reaction
- (C) Mole ratio of Cl_2O_7 , ClO_2 and O_2 during a chemical reaction at any instant (excluding any negative sign) are 2, 4 and 3 respectively
- (D) The ratio of change in number of moles of Cl_2O_7 , ClO_2 and O_2 is 2 : 4 : 3 (excluding any negative sign)

Ans. (D)

Sol. It follows directly from definition of stoichiometry.

Ex.13 Calculate the weight of iron which will be converted into its oxide by the action of 36 g of steam.

Ans. 84 g

Sol. Mole ratio of reaction suggests,

$$\text{Mole of Fe} = \frac{3}{4} \quad \text{mol of H}_2\text{O}$$

$$= \frac{3}{4} \times \frac{36}{18} = \frac{3}{2}$$

$$\text{wt. of Fe} = \frac{3}{2} \times 56 = 84 \text{ g}$$

Ex.14 When Dinitrogen pentaoxide (N_2O_5 , a white solid) is heated, it decomposes into nitrogen dioxide and oxygen.

If a sample of N_2O_5 produces 1.6 g O_2 , then how many grams of NO_2 are formed ?

(A) 9.2 g (B) 4.6 g (C) 2.3 g (D) 18.4 g

Ans. (A)

Sol. $\text{N}_2\text{O}_5(\text{s}) \longrightarrow 2\text{NO}_2(\text{s}) + \frac{1}{2} \text{O}_2$ (Balanced reaction)

$$\frac{\text{Mole of O}_2}{1/2} = \frac{\text{Mole of NO}_2}{2}$$

$$\frac{1.6}{32} \times 2 \times 2 = \text{Mole of NO}_2 = 0.2$$

$$\text{wt of NO}_2 = 0.2 \times 46 = 9.2 \text{ g.}$$

(c) Mass - volume analysis :

Now again consider decomposition of KClO_3

mass volume ratio : $2 \times 122.5 \text{ g} : 2 \times 74.5 \text{ g} : 3 \times 22.4 \text{ L at STP}$

we can use two relation for volume of oxygen

$$\frac{\text{Mass of KClO}_3}{\text{volume of O}_2 \text{ at STP}} = \frac{2 \times 122.5 \text{ g}}{3 \times 22.4 \text{ L}} \quad \dots(\text{i})$$

$$\text{and} \quad \frac{\text{Mass of KCl}}{\text{volume of O}_2 \text{ at STP}} = \frac{2 \times 74.5 \text{ g}}{3 \times 22.4 \text{ L}} \quad \dots(\text{ii})$$

Ex.15 When oxygen gas is passed through Siemen's ozoniser, it completely gets converted into ozone gas. The volume of ozone gas produced at 1 atm and 273K, if initially 96 g of oxygen gas was taken, is :

(A) 44.8 L

(B) 89.6 L

(C) 67.2 L

(D) 22.4 L

Ans. (A)

Sol. $3\text{O}_2 \longrightarrow 2\text{O}_3$

$$\text{Mole} = \frac{96}{32} = 3 \quad \text{mole} = 2$$

Volume of O_3 gas at 1 atm and 273K = $2 \times 22.4 = 44.8$ L

4.2 LIMITING REAGENT:

Many a time, reactions are carried out with the amounts of reactants that are different than the amounts as required by a balanced chemical reaction. In such situations, one reactant is in more amount than the amount required by balanced chemical reaction. The reactant which is present in the least amount gets consumed after sometime and after that further reaction does not take place whatever be the amount of the other reactant. Hence, the reactant, which gets consumed first, limits the amount of product formed and is, therefore, called the limiting reagent.

The reactant which consumed first into the reaction when we are dealing with balance chemical equation then if number of moles of reactants are not in the ratio of stoichiometric coefficient of balanced chemical equation, then there should be one reactant which should be limiting reactant.

Ex.16 Six mole of Na_2CO_3 is reacted with 4 moles of HCl solution. Find the volume of CO_2 gas produced at STP. The reaction is

Sol. From the reaction :

gives moles

3 mol 6 mol

given mole ratio

1 : 2

Stoichiometric coefficient ratio

1 : 2

See here given number of moles of reactants are not in stoichiometric coefficient ratio. Therefore there should be one reactant which consumed first and becomes limiting reagent.

But the question is how to find which reactant is limiting, it is not very difficult you can easily find it. According to the following method.

How to find limiting reagent:**Step : I**

Divide the given moles of reactant by the respective stoichiometric coefficient of that reactant.

Step : II

See for which reactant this division comes out to be minimum. The reactant having minimum value is limiting reagent.

Step : III

Now once you find limiting reagent then your focus should be on limiting reagent

From

Step I & II

Na_2CO_3

HCl

$$\frac{6}{1} = 6$$

$$\frac{4}{2} = 2 \text{ (Division in minimum)}$$

- HCl is limiting reagent

From Step III

$$\text{From } \frac{\text{Mole of HCl}}{2} = \frac{\text{Mole of CO}_2 \text{ produced}}{1}$$

- Mole of CO₂ produced = 2 moles
- Volume of CO₂ produced at S.T.P. = $2 \times 22.7 = 45.4$ L

C is limiting reagent.

moles of A₄B₂C₃ is 0.48.

Ex.18 A 5 g mixture of SO₂ and O₂ gases is reacted to form SO₃ gas. What should be the mass ratio of SO₂ and O₂ gases in mixture to obtain maximum amount of SO₃ gas :

- (A) 4 : 1 (B) 3 : 2 (C) 2 : 3 (D) 1 : 4

Ans. (A)

Sol. For maximum amount of product, the reactants should be present in their stoichiometric ratio.

mass x 5 - x

mole $\frac{x}{64}$ $\frac{5-x}{32}$

$$\text{So, } \frac{\left(\frac{x}{64}\right)}{\left(\frac{5-x}{32}\right)} = 2 : 1$$

Therefore, $x = 4$

$m_{\text{SO}_2} : m_{\text{O}_2} = 4 : 1$.

Ex.19 Calculate the weight of FeO from 4 g VO and 5.75 g of Fe₂O₃. Also report the limiting reactant.

Ans. Weight of FeO formed = 5.17 g

Sol. Balanced equation $2\text{VO} + 3\text{Fe}_2\text{O}_3 \rightarrow 6\text{FeO} + \text{V}_2\text{O}_5$

Moles before reaction	$\frac{4}{67}$	$\frac{5.75}{160}$	0	0
=	0.05970	0.03590		

$$\text{Moles after reaction} \quad (0.05970 - 0.0359) \quad 0 \quad \left(\frac{6}{5} \times 0.0359\right) \quad \left(\frac{1}{3} \times 0.0359\right)$$

As 2 moles of VO react with 3 moles of Fe_2O_3

- $0.05970 \text{ g moles of VO} = \frac{3}{2} \times 0.05970 = 0.08955 \text{ moles of Fe}_2\text{O}_3$

Moles of Fe_2O_3 available = 0.0359 only

Hence, Fe_2O_3 is the limiting reagent.

$$\text{Moles of FeO formed} = \frac{6}{3} \times 0.0359$$

- Weight of FeO formed = $0.0359 \times 2 \times 72 = 5.17 \text{ g}$

$$\left(\frac{n_{\text{FeO}}}{n_{\text{Fe}_2\text{O}_3}} = \frac{6}{3}\right) = n_{\text{FeO}} = \frac{6}{3} \times n_{\text{Fe}_2\text{O}_3}$$

(A) 49 g (B) 98 g (C) 61 g (D) 34.3 g

4.3 PRINCIPLE OF ATOM CONSERVATION (POAC):

Infect POAC is nothing but the conservation of mass, expressed before in the concepts of atomic theory. And if atoms are conserved, moles of atoms shall also be conserved.

The principle is fruitful for the students when they don't get the idea of balanced chemical equation in the problem.

This principle can be under stand by the following example.

Consider the decomposition of $\text{KClO}_3 (\text{s}) \longrightarrow \text{KCl} (\text{s}) + \text{O}_2 (\text{g})$ (unbalanced chemical reaction)

Apply the principle of atom conservation (POAC) for K atoms.

Moles of K atoms in reactant = moles of K atoms in products

or moles of K atoms in KClO_3 = moles of K atoms in KCl

Now, since 1 molecule of KClO_3 contains 1 atom of K

or 1 mole of KClO_3 contains 1 mole of K, similarly 1 mole of KCl contains 1 mole of K

Thus, moles of K atoms in $\text{KClO}_3 = 1 \times \text{moles of } \text{KClO}_3$

and moles of K atoms in KCl = $1 \times \text{moles of KCl}$

- moles of KClO_3 = moles of KCl

$$\text{or } \frac{\text{wt. of } \text{KClO}_3 \text{ in g}}{\text{mol. wt. of } \text{KClO}_3} = \frac{\text{wt. of KCl in g}}{\text{mol. wt. of KCl}}$$

- * The above equation gives the mass-mass relationship between KClO_3 and KCl which is important in stoichiometric calculations.

Again, applying the principle of atom conservation for O atoms,

moles of O in $\text{KClO}_3 = 3 \times \text{moles of } \text{KClO}_3$

moles of O in $\text{O}_2 = 2 \times \text{moles of } \text{O}_2$

- $3 \times \text{moles of } \text{KClO}_3 = 2 \times \text{moles of } \text{O}_2$

$$\text{or } \frac{\text{wt. of } \text{KClO}_3}{\text{mol. wt. of } \text{KClO}_3} = 2 \times \frac{\text{vol. of } \text{O}_2 \text{ at NTP}}{\text{standard molar vol. (22.4 lt)}}$$

The above equations thus give the mass-volume relationship of reactants and products.

Ex.20 27.6g K_2CO_3 was treated by a series of reagents so as to convert all of its carbon to $\text{K}_2\text{Zn}_3 [\text{Fe}(\text{CN})_6]_2$. Calculate the weight of the product.

[mol. wt. of $\text{K}_2\text{CO}_3 = 138$ and mol. wt. of $\text{K}_2\text{Zn}_3 [\text{Fe}(\text{CN})_6]_2 = 698$]

Ans. 11.6 g

Sol. Here we have not knowledge about series of chemical reactions but we known about initial reactant and final product accordingly

Since C atoms are conserved, applying POAC for C atoms,

Moles of C in K_2CO_3 = moles of C in $K_2Zn_3 [Fe(CN)_6]_2$

$1 \times \text{moles of } K_2CO_3 = 12 \times \text{moles of } K_2Zn_3 [Fe(CN)_6]_2$

(Q 1 mole of K_2CO_3 contains 1 moles of C)

$$\frac{\text{wt. of } K_2CO_3}{\text{mol. wt. of } K_2CO_3} = 12 \frac{\text{wt. of the product}}{\text{mol. wt. of product}}$$

$$\text{wt. of } K_2Zn_3 [Fe(CN)_6]_2 = \frac{27.6}{138} \frac{698}{12} = 11.6 \text{ g}$$

Ex.21 In a gravimetric determination of P of an aqueous solution of dihydrogen phosphate in $H_2PO_4^-$ is treated with a mixture of ammonium and magnesium ions to precipitate magnesium ammonium phosphate, $Mg(NH_4)PO_4 \cdot 6H_2O$. This is heated and decomposed to magnesium pyrophosphate, $Mg_2P_2O_7$. A solution of $H_2PO_4^-$ yielded 2.054 g of $(Mg_2P_2O_7)$. What weight of NaH_2PO_4 was present originally?

Ans. 2.22 g

Sol. $NaH_2PO_4 + Mg^{2+} + NH_4^+ + \frac{3}{4} Mg(NH_4)PO_4 \cdot 6H_2O \xrightarrow{\Delta} Mg_2P_2O_7$

As P atoms are conserved, applying POAC for P atoms, moles of P in NaH_2PO_4 = Moles of P in $Mg_2P_2O_7$

• $1 \times \text{Moles of } NaH_2PO_4 = 2 \times \text{Moles of } Mg_2P_2O_7$

$$\bullet \frac{W_{NaH_2PO_4}}{M_{NaH_2PO_4}} = 2 \times \frac{W_{Mg_2P_2O_7}}{M_{Mg_2P_2O_7}} \Rightarrow \frac{W_{NaH_2PO_4}}{120} = 2 \times \frac{2.054}{222}$$

• $W_{NaH_2PO_4} = 2.22 \text{ g}$

4.4 PERCENTAGE YIELD:

In general, in any chemical reaction, the amount of product formed is always less than the calculated amount due to reversibility in the chemical reaction. Therefore, yield of a chemical reaction (Y) comes into picture and is given by :

$$\text{The percentage yield of product} = \frac{\text{actual yield}}{\text{the theoretical maximum yield}} \times 100$$

Ex.22 In a certain operation 358 g of $TiCl_4$ is reacted with 96 g of Mg. Calculate % yield of Ti if 32 g of Ti is actually obtained [At. wt. Ti = 48, Mg = 24]

(A) 35.38 %

(B) 66.6 %

(C) 100 %

(D) 60 %

Ans. (A)

Ex.23 0.05 mole of LiAlH_4 in ether solution was placed in a flask containing 74g (1 mole) of t-butyl alcohol. The product $\text{LiAlHC}_{12}\text{H}_{27}\text{O}_3$ weighed 12.7 g. If Li atoms are conserved, the percentage yield is : (Li = 7, Al = 27, H = 1, C = 12, O = 16).

- (A) 25% (B) 75% (C) 100% (D) 15%

Ans. (C)

0.05 mole 12.7 gram

$$= \frac{12.7}{254} = 0.05 \text{ mole}$$

Li atom remain conserved so

No. of mole of LiAlH_4 = No. of mole of $\text{LiAlHC}_{12}\text{H}_{27}\text{O}_3$

So No. of mole of $\text{LiAlHC}_{12}\text{H}_{27}\text{O}_3 = 0.05$

$$\% \text{ yield} = \frac{0.05}{0.05} \times 100 = 100\%$$

4.5 PERCENTAGE PURITY:

Ex.24 How much marble of 90.5 % purity would be required to prepare 10 litres of CO_2 at 1 atm, 0°C when the marble is acted upon by dilute HCl ?

Ans. 49.326 g

100 g 22.4 litre

22.4 L of CO_2 at STP will be obtained from 100 g of CaCO_3

- 10 L of CO_2 will be obtained from pure $\text{CaCO}_3 = \frac{100}{22.4} \times 10 = 44.64 \text{ g}$
- Impure marble required = $\frac{100}{90.5} \times 44.64 = 49.326 \text{ g}$

4.6 SEQUENTIAL REACTIONS:

This reaction is defined as that reaction which proceeds from reactants to final products through one or more intermediate stages. The overall reaction is a result of several successive or consecutive steps.

Example: $A \rightarrow B \rightarrow C$

Ex.25 Minimum amount of Ag_2CO_3 (s) required to produce sufficient oxygen for the complete combustion of C_2H_2 which produces 11.2 L of CO_2 at 1 atm and 273K after combustion is: [Ag = 108]

Ans. 345 g

By Stoichiometry of reaction

$$\text{Moles of CO}_2 \text{ formed} = \frac{11.2}{22.4} = \frac{1}{2}$$

$$\text{Moles of O}_2 \text{ required} = \frac{5}{4} \times \frac{1}{2} = \frac{5}{8}$$

$$\text{Moles of Ag}_2\text{CO}_3 \text{ required} = 2 \times \frac{5}{8} = \frac{5}{4}$$

$$\text{Mass of Ag}_2\text{CO}_3 \text{ required} = \frac{5}{4} \times 276 = 345 \text{ g}$$

Ex.26 NX is produced by the following step of reactions

(Take at wt of M = 56, N=23, X = 80)

(A) 42 g (B) 56 g (C) 52g (D) 64 g

Ans. (A)

$$\text{mole of NX} = \frac{206}{103} = 2$$

POAC for X Atom :

$$\text{No. of X atom in } M_3X_8 = \text{No. of X Atom in NX}$$

$$8 [\text{No. of mole of } M_3X_8] = 1 [\text{No. of mole of NX}]$$

$$\text{No. of mole of } M_3X_8 = \left[\frac{2}{8} \right] = \frac{1}{4} \text{ mole}$$

Now POAC for M Atom

$$3 [\text{No. of mole of } M_3X_8] = 1 \times [\text{No. of Mole of M}]$$

$$3 \times \frac{1}{4} = \text{No. of mole of M}$$

$$\text{weight of M atom} = \frac{3}{4} \times 56 = 42 \text{ gram}$$

Ex.27 The following process has been used to obtain iodine from oil-field brines in California.

How many grams of $AgNO_3$ are required in the first step for every 254 kg I_2 produced in the third

- (A) 340 kg (B) 85 kg (C) 68 kg (D) 380 kg

Ans. (A)

Sol. Balanced equation :

From (3)

$$\frac{\text{mole of } I_2}{2} = \frac{\text{mole of } FeI_2}{2}$$

$$\frac{\text{mole of } FeI_2}{1} = \frac{\text{mole of } AgI}{2}$$

$$\frac{\text{mole of } AgI}{1} = \frac{\text{mole of } AgNO_3}{1}$$

$$\text{mole of } I_2 = (\text{mole of } FeI_2)$$

$$= \left(\frac{\text{mole of } AgI}{2} \right) = \left(\frac{\text{mole of } AgNO_3}{2} \right)$$

$$\frac{254 \times 10^3}{254} = \frac{\text{mole of AgNO}_3}{2}$$

$$2 \times 10^3 = \text{mole of AgNO}_3 = \frac{\text{mass of AgNO}_3}{\text{molar mass of AgNO}_3}$$

$$\text{mass of AgNO}_3 = 170 \times (2 \times 10^3) \text{ g} = 340 \times 10^3 \text{ g} = 340 \text{ kg.}$$

4.7 PARALLEL REACTIONS:

The reactions in which a substance reacts or decomposes in more than one way are called parallel or side reactions.

Example: $A \longrightarrow B$

$A \longrightarrow C$

Ex.28 Find out moles of CO_2 & CO produced by combustion of 2 mol carbon with 1.25 O_2 leaving number residue:

Ans. $\text{CO}_2 = 0.5 \text{ mol}, \text{CO}_2 = 1.5 \text{ mol}$

Sol. $\text{C} + \text{O}_2 \longrightarrow \text{CO}_2$

x x x

$\text{C} + \frac{1}{2} \text{O}_2 \longrightarrow \text{CO}$

$2-x \quad \frac{2-x}{2} \quad 2-x$

$$x + 1 - \frac{x}{2} = 1.25$$

$$\frac{x}{2} = \frac{125}{100}$$

$$x = 0.5 \text{ mol}, \quad \text{CO}_2 = 0.5 \text{ mol}, \text{CO}_2 = 1.5 \text{ mol}$$

4.8 MIXTURE ANALYSIS:

The analysis of a chemical reaction is generally carried out in the form of mass of reacting species taking part in a given reaction (gravimetric analysis) or in terms of concentrations of reacting species taking part in a given reaction (volumetric analysis). In Gravimetric Analysis, we generally analyse reactions such as : decomposition of compounds under heat to produce a residue and a gas, or displacement reactions, action of acids on metals, or simple balanced chemical equations involving Weight (solid) – Volume (gas) relationships. In Volumetric Analysis, we generally analyse Neutralisation and Redox Titrations involving aqueous solutions in general.

(M = Na, K, Rb, Cs)

- (ii) All the carbonates of alkaline earth metals are thermally unstable and decompose on heating as follow.

- (iii) Bicarbonates of both alkali metals and alkaline earth metals are decomposed at relatively low temperature as follow.

Ex.29 A sample of 3 g containing Na_2CO_3 and $NaHCO_3$ loses 0.248 g when heated to $300^\circ C$, the temperature at which $NaHCO_3$ decomposes to Na_2CO_3 , CO_2 and H_2O . What is the percentage of Na_2CO_3 in the given mixture?

Ans. 77.48%

Sol. The loss in weight is due to removal of CO_2 and H_2O which escape out on heating.

wt. of Na_2CO_3 in the product = $3.00 - 0.248 = 2.752$ g

Let wt. of Na_2CO_3 in the mixture be x g

wt. of $NaHCO_3 = (3.00 - x)$ g

Since Na_2CO_3 in the products contains x g of unchanged reactant Na_2CO_3 and rest produced from $NaHCO_3$.

The wt. of Na_2CO_3 produced by $NaHCO_3 = (2.752 - x)$ g

(3.0 - x) (2.752 - x)

Applying POAC for Na atom

$$1 \times \text{moles of } NaHCO_3 = 2 \times \text{moles of } Na_2CO_3 \Rightarrow \frac{(3-x)}{84} = 2x \frac{(2.752-x)}{106}$$

$$x = 2.3244 \text{ g}$$

$$\% \text{ of } Na_2CO_3 = \frac{2.3244}{3} \times 100 = 77.48\%$$

- (A) 32.1 % (B) 16.2 % (C) 21.8 % (D) 11.0 %

$$\frac{x}{111} \text{ mol} \quad \frac{x}{111} \text{ mol} \quad \frac{x}{111} \text{ mol}$$

$$\text{Mole of CaO} = \frac{1.62}{56}$$

$$\frac{x}{111} = \frac{1.62}{56}$$

$$x = 3.21 \text{ g}$$

$$\% \text{ of CaCl}_2 = \frac{3.21}{10} \times 100 = 32.1 \%$$

5. DENSITY:

It is of two type.

1. Absolute density 2. Relative density

(a) For liquid and solids

$$\text{Absolute density} = \frac{\text{mass}}{\text{volume}}$$

$$\text{Relative density or specific gravity} = \frac{\text{density of the substance}}{\text{density of water at } 4^\circ\text{C}}$$

(b) For gasses:

$$\text{Absolute density (mass / volume)} = \frac{PM}{RT}$$

where P is pressure of gas, M = mol. wt. of gas, R is the gas constant, T is the temperature.

Relative density and Vapour density:

Vapour density is defined as the density of the gas with respect to hydrogen gas at the same temperature and pressure.

$$\text{Vapour density} = \frac{d_{\text{gas}}}{d_{\text{H}_2}} = \frac{PM_{\text{gas}} / RT}{PM_{\text{H}_2} / RT}$$

$$\text{V.D.} = \frac{M_{\text{gas}}}{M_{\text{H}_2}} = \frac{M_{\text{gas}}}{2} \Rightarrow \boxed{M_{\text{gas}} = 2 \text{V.D.}}$$

Ans. (A)

Sol. $1 \times 10^3 \text{ kg/m}^3 = 1 \text{ g/mL}$. [Since, $1 \text{ m}^3 = 10^6 \text{ cm}^3 = 10^6 \text{ mL}$].

$$d = \frac{\text{mass}}{\text{volume}}, \text{ So, volume} = \frac{3 \times 10^{-23} \text{ g}}{1 \text{ (g / mL)}} = 3 \times 10^{-23} \text{ mL.}$$

6. AVERAGE/ MEAN ATOMIC MASS :

The weighted average of the isotopic masses of the element's naturally occurring isotopes.

$$\text{Mathematically, average atomic mass of X (A}_x\text{)} = \frac{a_1x_1 + a_2x_2 + \dots + a_nx_n}{100}$$

Where : $a_1, a_2, a_3 \dots$ atomic mass of isotopes.

and $x_1, x_2, x_3 \dots$ mole % of isotopes.

Ex.34 Naturally occurring chlorine is 75.53% Cl^{35} which has an atomic mass of 34.969 amu and 24.47% Cl^{37} which has a mass of 36.966 amu. Calculate the average atomic mass of chlorine -

$$= 35.5 \text{ amu.}$$

6.1 AVERAGE MOLAR MASS OR AVERAGE GRAM MOLECULAR MASS:

$$= \frac{n_1M_1 + n_2M_2 + \dots + n_nM_n}{n_1 + n_2 + \dots + n_n}$$

Where : $M_1, M_2, M_3 \dots$ are molar masses.

$n_1, n_2, n_3 \dots$ moles of substances.

Average molecule wt. = $\frac{\sum n_i M_i}{\sum n_i}$ where n_i = no. of moles of compound, m_i = molecular mass of compound

Ex.35 The molar composition of polluted air is as follows :

What is the average molecular weight of the given polluted air ?

Ans. 29.48

Sol. $M_{\text{avg}} = \frac{16 \times 32 + 80 \times 28 + 44 \times 3 + 64 \times 1}{100} = \frac{512 + 2240 + 132 + 64}{100} = \frac{2948}{100} = 29.48$

6.2 DEGREE OF DISSOCIATION (A):

Degree of dissociation represents the fraction of one mole dissociated into the products.

(Defined for one mole of substance)

So, $a = \text{no. of moles dissociated} / \text{initial no. of moles taken}$
 $= \text{fraction of moles dissociated out of 1 mole.}$

Note : % dissociation = $a \times 100$

Suppose 5 moles of PCl_5 is taken and if 2 moles of PCl_5 dissociated then $a = \frac{2}{5} = 0.4$

6.3 RELATIONSHIP BETWEEN AVERAGE MOLAR MASS & DEGREE OF DISSOCIATION (A):

Average molecular weight of mixture(g) = $\frac{\text{molecular weight of } A_n(g)}{\text{total no. of moles at equilibrium}}$

$$= \frac{a.M_{th}}{a(1 + (n - 1)\alpha)}$$

$$M_{\text{avg}} = \frac{M_{th}}{[1 + (n - 1)\alpha]}$$

where M_{th} = theoretical molecular weight (n = atomicity)

Ex.36 NH_3 decomposes into N_2 & H_2 . If average molar mass of reaction mixture is 10 then, find α ?

Ans. 0.7

$$1-\alpha \quad \frac{\alpha}{2} \quad \frac{3\alpha}{2}$$

$$10 = \frac{17}{1-\alpha + \frac{\alpha}{2} + \frac{3\alpha}{2}}$$

$$10 = \frac{17}{1+\alpha}$$

$$1 + \alpha = 1.7$$

$$\alpha = 0.7$$

7. PERCENTAGE COMPOSITION AND MOLECULAR FORMULA :

Here we are going to find out the percentage of each element in the compound by knowing the molecular formula of compound.

We know that according to law of definite proportion any sample of a pure compound always possess constant ratio with their combining elements.

Example:

Every molecule of ammonia always has formula NH_3 irrespective of method of preparation or sources. i.e. 1 mole of ammonia always contains 1 mol of N and 3 mole of H. In other words 17 g of NH_3 always contains 14 g of N and 3 g of H. Now find out % of each element in the compound.

$$\text{Mass \% of N in NH}_3 = \frac{\text{Mass of N in 1 mol NH}_3}{\text{Mass of 1 mol of NH}_3} \times 100 = \frac{14\text{g}}{17} \times 100 = 82.35 \%$$

$$\text{Mass \% of H in NH}_3 = \frac{\text{Mass of H in 1 mol NH}_3}{\text{Mass of 1 mol of NH}_3} \times 100 = \frac{3}{17} \times 100 = 17.65 \%$$

7.1. EMPIRICAL AND MOLECULAR FORMULA:

We have just seen that knowing the molecular formula of the compound we can calculate percentage composition of the elements. Conversely if we know the percentage composition of the elements initially, we can calculate the relative number of atoms of each element in the molecules of the compound. This gives as the empirical formula of the compound. Further if the molecular mass is known then the molecular formula can be easily determined.

Thus, the empirical formula of a compound is a chemical formula showing the relative number of atoms in the simplest ratio, the molecular formula gives the actual number of atoms of each element in a molecule.

Empirical formula: An empirical formula represents the simple whole number ratio of various atoms present in a compound,

Molecular formula: whereas, the molecular formula shows the exact number of different types of atoms present in a molecule of a compound

The molecular formula is generally an integral multiple of the empirical formula.

That is:

$$\text{molecular formula} = \text{empirical formula} \times n$$

$$\text{where } n = \frac{\text{molecular formula mass}}{\text{empirical formula mass}}$$

Ex.37 An organic substance containing carbon, hydrogen and oxygen gave the following percentage composition.

C = 40.687 % ; H = 5.085 % and O = 54.228 %

The molecular weight of the compound is 118. Calculate the molecular formula of the compound.

Ans. $\text{C}_4\text{H}_6\text{O}_4$

Sol. Step -1

To calculate the empirical formula of the compound.

Element	Symbol	Percentage of element	At. mass of element	Relative no. of atoms = $\frac{\text{Percentage}}{\text{At.mass}}$	Simplest Atomic ratio	Simplest whole atomic ratio
Carbon	C	40.687	12	$\frac{40.687}{12} = 3.390$	$\frac{3.390}{3.389} = 1$	2
Hydrogen	H	5.085	1	$\frac{5.085}{1} = 5.035$	$\frac{5.085}{3.389} = 1.5$	3
Oxygen	O	54.228	16	$\frac{54.228}{16} = 3.389$	$\frac{3.389}{3.389} = 1$	2

Step - 2

To calculate the empirical formula mass.

The empirical formula of the compound is $C_2H_3O_2$.

Empirical formula mass

$$= (2 \times 12) + (3 \times 1) + (2 \times 16) = 59.$$

Step - 3

To calculate the value of 'n'

$$n = \frac{\text{molecular mass}}{\text{Empirical formula mass}} = \frac{118}{59} = 2$$

Step - 4

To calculate the molecular formula of the salt

Molecular formula = $n \times (\text{Empirical formula})$

$$= 2 \times C_2H_3O_2 = C_4H_6O_4$$

Thus the molecular formula is $C_4H_6O_4$.

Ex.38 Chlorophyll the green colouring material of plants contains 3.68 % of magnesium by mass. Calculate the number of magnesium atom in 5.00 g of the complex.

Sol. Mass of magnesium in 5.0 g of complex = $\frac{3.68}{100} \times 5.00 = 0.184 \text{ g}$

Atomic mass of magnesium = 24

24 g of magnesium contain = 6.023×10^{23} atoms

$$0.184 \text{ g of magnesium would contain} = \frac{6.023 \times 10^{23}}{24} \times 0.184 = 4.617 \times 10^{21} \text{ atom}$$

Therefore, 5.00 g of the given complex would contain 4.617×10^{21} atoms of magnesium.

Ex.39 A sample of $CaCO_3$ has Ca = 40%, C = 12% and O = 48% by mass. If the law of constant proportions is true, then the mass of Ca in 5 g of $CaCO_3$ obtained from another source will be:

- (A) 0.2 g (B) 2 g (C) 0.6 g (D) Cannot be determined

Ans. (B)

Sol. Mass of Ca = $5 \times \frac{40}{100} = 2 \text{ g.}$

8. EXPERIMENTAL METHODS TO DETERMINE ATOMIC & MOLECULAR MASSES**8.1** For determination of atomic mass :**(a)** Dulong's & Pettit's law :

In case of metals, it is observed that product of atomic weight and specific heat capacity is constant.

The equation connecting the two parameters was given by Dulong's and Petit's Law.

Atomic weight of metal \times specific heat capacity ($\text{cal/gm}^\circ\text{C}$) = 6.4.

It should be remembered that this law is an empirical observation and this gives an approximate value of atomic weight. Also this law can be applied only to metals at high temperature conditions only.

8.2 Experimental methods for molecular mass determination.**(a)** Victor Meyer's Method**(b)** Silver Salt Method**(c)** Chloroplatinate Salt Method**(a) Victor Meyer's Method:** (Applicable for volatile substance)

A known mass of the volatile substance taken in the Hoffmann's bottle and is vapourised by throwing the Hoffmann's bottle into the Victor Meyer's tube. The vapour displaces an equal volume of the moist air. Which vapours is measured at the room temperature and atmospheric pressure. The barometric pressure and the room temperature is recorded. Following diagram gives the experimental set-up for the Victor-Meyer's process.

Calculation involved

Let the mass of the substance taken by = $W\text{g}$

Volume of moist vapours collected = $V\text{cm}^3$

Room temperature = $T^\circ\text{K}$

Barometric pressure = $P\text{ mm}$

Aqueous tension at $T^\circ\text{K}$ = $p\text{ mm}$

Pressure of dry vapour = $(P - p)\text{ mm}$

Calculation of molecular mass (M)

$$\frac{(P-p)}{760} \times \frac{V}{1000} = \frac{w}{M} \times RT$$

$$M = \frac{w \times RT \times 760 \times 1000}{(P-p) \times V}$$

(b) Silver salt Method: (A used for organic acids)

A known mass of the acid is dissolved in water followed by the subsequent addition of silver nitrate solution till the precipitation of silver salt is complete. The precipitate is separated, dried, weighed

and ignited till decomposition is complete. The residue of pure silver left behind is weighed. Calculations involved

Let the mass of the silver salt formed = W g

The mass of Ag formed = x g

Let us understand to calculations by considering the monobasic acid MX.

Mass of the salt that gives x gm of Ag = W g

Mass of the salt gives 108g (1g-atom) of Ag = $\frac{108W}{x}$ g

Molar mass of salt = $\frac{108W}{x}$ g

Molar mass of acid = (Molar mass of salt) – (Atomic mass of Ag) + (Atomic mass of H)

$$= \frac{108W}{x} - 108 + 1 = \left(\frac{108W}{x} - 107 \right) \text{g mol}^{-1}$$

For polybasic acid of the type H_nX (n is basicity)

Mass of the silver that gives x g of Ag = W g

$$\text{Mass of the silver that gives } (108n \text{ g}) \text{ of Ag} = \frac{108nW}{x} \text{ g}$$

$$\text{Molar mass of salt} = \frac{108 \times nW}{x} \text{ g}$$

$$\text{Molar mass of acid} = (\text{molar mass of salt}) = \frac{108 \times nW}{x} - n \times 108 - n \times 1$$

$$= n \left(\frac{108W}{x} - 107 \right) \text{ g mol}^{-1}$$

(c) **Platinic chloride Method :** (Applicable for finding the molecular masses of organic bases).

A known mass of organic base is allowed to react with chloroplatinic acid (H_2PtCl_6) in conc. HCl to form insoluble platinic chloride. The precipitate of platinic chloride is separated, dried, weighed and subsequently ignited till decomposition is complete. The residue left is platinum which is again weighed. The molecular mass is then calculated by knowing the mass of the platinic chloride salt and that of platinum left.

If B represents the molecule of monoacidic organic base, then the formula of platinic chloride salt is

Let the mass of platinic chloride salt = W g, The mass of the platinum residue left = x g

It may be noted that salt formed with diacidic base would be $\text{B}_2(\text{H}_2\text{PtCl}_6)_2$

With triacidic base it would be $\text{B}_2(\text{H}_2\text{PtCl}_6)_3$ and with polyacidic base would be $\text{B}_2(\text{H}_2\text{PtCl}_6)_n$.

$$\text{Mass of salt which gives 195 g (1 g-atom) of Pt} = \frac{W \times 195}{x} \text{ g}$$

$$\text{Molar mass of salt} = \frac{W \times 195}{x} \text{ g mol}^{-1}$$

Now from the formula $\text{B}_2(\text{H}_2\text{PtCl}_6)$

Molar mass of salt = (2 × molar mass of base) + (Molar mass of H_2PtCl_6)

$$\text{Molar mass of base} = \frac{1}{2} (\text{molar mass of salt} - \text{Molar mass of } \text{H}_2\text{PtCl}_6)$$

$$= \frac{1}{2} \left(\frac{W \times 195 \times n}{x} - n \times 410 \right) = \frac{n}{2} \left(\frac{W \times 195}{x} - 410 \right) \text{ g mol}^{-1}$$

\therefore 1 gm of proton contains = 1 mole

\therefore 1000 gm of proton contains = 10^3 mole

4. Mass of 1 e^- = 9.1×10^{-31} kg

Mass of 1 mole e^- = $9.1 \times 10^{-31} \times 6 \times 10^{23} = 54.6 \times 10^{-8}$ kg/mol

5. $n_{CO_2} = \frac{44}{44} = 1$ mole

8. $n_{NO_3^-} = \frac{3.1 \times 10^{-3}}{62 \times 10}$

$= 0.5 \times 10^{-4}$

$= 5 \times 10^{-5}$

Number of electrons in 3.1 mg $NO_3^\ominus = 5 \times 10^{-5} \times 32 \times 6.022 \times 10^{23} = 9.6 \times 10^{20}$.
